System Validation Report

Task Manager Application | Team 4 | Test execution: 6 November 2026

1. System validation results

Validation	Result	Evidence
Frontend lint	PASS	npm run lint; no ESLint errors
Frontend production build	PASS	Vite build completed
Backend startup	PASS	API started on port 5000
Database connectivity	PASS	/api/health returned OK; task_manager
API integration suite	PASS	18 passed, 0 failed
Registration and login	PASS	Valid and invalid credential cases
Task creation and listing	PASS	Created task then retrieved it
Task status update	PASS	Valid update accepted; invalid status rejected
User isolation	PASS	Second user could not view/update first user's task

2. Scope limitations and defects/gaps

The current local backend task router contains create (POST /), list (GET /), and status update (PUT /:id/status) endpoints. It does not define task-detail edit, delete, or assignment routes.

The inspected tasks table has id, user_id, title, description, priority, deadline, status, created_at, and updated_at columns. It has no assignee_id column.

Therefore edit-details, deletion, and assignment were not part of the 18 passing checks and remain unimplemented in the inspected version. Earlier exploratory tests for those endpoints returned 404; those exploratory failures are not included in the corrected 18-test suite.

3. Conclusion

The executed API integration suite passed 18/18 checks, and the backend health endpoint confirmed PostgreSQL connectivity. This is strong evidence for the implemented API scope, but it does not demonstrate completion of all features described in the broader test plan.
